1 Overview of the proposed approach

\textbf{Algorithm 1:} Dynamic super-ray algorithm

\begin{itemize}
\item \textbf{Data:} Input light field frame $LF^f$
\item \textbf{Result:} Super-ray assignments $A^f$
\item \textbf{if} $f == \text{first frame}$ \textbf{then}
\begin{itemize}
\item Compute $A^f$ as in [1]
\end{itemize}
\textbf{else}
\begin{itemize}
\item Move centroids with $(\delta^x_c, \delta^d_c)$ (Sec. 4.1)
\item Delete and create centroids (Sec. 4.2)
\end{itemize}
\textbf{for} 5 iterations \textbf{do}
\begin{itemize}
\item Do the assignment step Eq. 1
\item Do the update step (Sec 4.3)
\end{itemize}
\end{itemize}

2 Full cost volume computation for scene flow

For two consecutive light field frames $f$ and $f + 1$, one could estimate the scene flow $(\delta^x_c, \delta^d_c)$ at the centroid ray $r^f_c = (s_c, x_c)$ as

\[
(\delta^x_c, \delta^d_c) = \arg \min_{\delta^x, \delta^d} \sum_{s'} \Delta^B_{RGB}(r^{f+1}_c, r'^{f+1}_c)
\]

(1)

where $r^{f+1}_c = (s_c, x_c + \delta^x)$, $r'^{f+1}_c = (s', D^{d'}_{s'} + \delta^d(x_c + \delta^x))$ and $\Delta^B_{RGB}$ the color distance between two patches of size $B$ centered at $r^{f+1}_c$ and $r'^{f+1}_c$.

3 Quantitative Evaluation Detailed Results

Tab. 4 table summarizes the results we obtain on the Monka dataset in [3], using the different qualitative metrics in [2]:

- Achievable segmentation accuracy (ASA): segmentation accuracy obtained when every super-pixel is assigned the optimal ground truth label.
- Boundary recall (BR): ratio of superpixel boundary overlapping a real object boundary.
- Under-segmentation error (we use the Corrected Under-Segmentation error (CUE) as proposed in [4]): each superpixel is assigned to the ground-truth label with biggest overlap. The CUE is the ratio of pixels that lies inside of the superpixel but outside of its inside ground truth label.
- Temporal consistency (TC): using the ground truth optical flow \( \delta_x \), ratio of corresponding pixels that lies inside the same super-pixels from the two sets of assignments \( A_f \) and \( A_{f+1} \) in the light field reference view \( I \).

\[
TC(A) = \frac{1}{|I|} \sum_{x \in I} \Delta(A_f(x), A_{f+1}(x + \delta_x))
\]

where \( \Delta \) the Kronecker delta function.

We compare:

- The static super-rays in [3] (SR), put into correspondence such that TC is maximized (using the ground truth flow) between a reference frame (central) and the others.
- The proposed approach (DSR)

The test are carried out using the ground truth label, optical flow and disparity on the first 50 frames of each dataset. Note that we removed the flowerstorm and funnyworld camera2 sequences because the camera and objects movements were too unreasonable. The best result for each metric is in bold typeface.

Note that for some sequences, the movement of the camera is so violent that super-rays are not deleted/created fast enough to cover the dis-occluded areas (e.g. in eating camera2), resulting in loss of temporal consistency. The static super-ray case do not have this issue because the ground truth is used to establish the correspondences, so it is numerically advantaged in that scenario.

4 Qualitative Evaluation Parameters

As hyper-parameters, fixed for all the datasets, we use a down-sampling factor of 2 and a flow window of 30 pixels for the computation of the deep matches. The \( \delta_d \) search range is limited to 1/10 of the depth search range, given for each dataset. The depth block size is fixed to 11 × 11 pixels. The compactness parameter \( \lambda \) is fixed to 0.5 and \( \tau \) and \( p \) are fixed to 1.9 and 0.4 respectively. We generated 1500 super-rays for the Technicolor dataset and 2000 for the Fraunhofer dataset. These number of super-rays offer a good trade-off between segmentation accuracy and super-ray tolerance to occlusions (as discussed in [4]) for each of the datasets. Our dynamic super-rays are computed in the whole sequences without fragmenting them.
